## 1 Premessa

Nella presente Relazione Tecnica è riportata una **Valutazione Previsionale dell'impatto sull'atmosfera** dovuto alle emissioni di sostanze inquinanti che si sviluppano nelle condizioni di normale esercizio dell'attività presso l'impianto per la digestione anaerobica dei rifiuti della **"ASITE – Fermo Ambiente Servizi Impianti Tecnologici Energia"** sito in C.da San Biagio nel **Comune di Fermo (FM)**.

Lo studio è teso a verificare il rispetto dei limiti di concentrazione degli inquinanti nell'area prossima al sito in relazione alle emissioni in atmosfera convogliate attraverso:

1. **E1 – Scarico fossa impianto selezione R.U.;**
2. **E3 – Biofiltro sezione compostaggio R.U.;**
3. **E4 – I° Gruppo elettrogeno;**
4. **E5 – II° Gruppo elettrogeno;**
5. **E6 – Impianto compostaggio rifiuti organici;**
6. **E7 - Biofiltro capannone stoccaggio e preparazione F.O.R.S.U.;**
7. **E8 – Impianto di cogenerazione alimentato a biometano;**

Le valutazioni sono state condotte mediante simulazione effettuata, a partire dai dati di progetto, secondo la metodologia di seguito descritta:

1. Per caratterizzare le emissioni derivanti dai processi di trattamento dei materiali sono stati impiegati specifici fattori di emissione per le diverse attività esaminate, riportati e descritti nei paragrafi che seguono;
2. Per la simulazione di ricaduta al suolo degli inquinanti atmosferici è stato impiegato il modello di dispersione **"Gaussian Plume" SCREEN3 Vers. 96043** elaborato dalla **US-EPA** (United States - Environmental Protection Agency);
3. Al fine di simulare cautelativamente le situazioni più acute di impatto, sono state stimate le ricadute al suolo massime, in modalità **"Short Term"** (concentrazione media su 1 – 24h), degli inquinanti.

**Le ricadute provenienti dai punti di emissione E7 ed E8 sono state valutate e descritte nella relazione tecnica Prot. 127/14 VIATM del 27/03/2014. Ad essa si rimanda per i dettagli del caso e per i valori di ricaduta applicati nella presente valutazione.**

## 2 Dati di progetto

### 2.1 Area dell'insediamento

Il sito della della ASITE, sito in Loc. San Biagio nel Comune di Fermo, si estende su una superficie di oltre 10.000 m<sup>2</sup>.

L'area circostante lo stabilimento è a carattere tipicamente rurale con presenza di case sparse. In Fig. 1 è riportato un rilievo fotografico della zona interessata con, evidenziata, l'area del sito in esame.

*Fig. 1 – Fotorilievo del sito in esame.*

### 2.2 Descrizione dell'attività produttiva

La ASITE gestisce il Centro Integrato per la Gestione dei Rifiuti Urbani (CIGRU) del comprensorio del fermano occupandosi della gestione, trattamento e smaltimento dei rifiuti non pericolosi.

Le emissioni valutate nella presente valutazione sono riconducibili ai seguenti impianti:

1. **impianto di selezione e compostaggio dei rifiuti urbani "RU" (emissioni E1, E3);**
2. **impianto per la produzione di compost da rifiuti organici "RO" (emissione E6);**
3. **impianto di selezione e compostaggio dei rifiuti urbani "BI" (emissioni E4, E5);**

nonché all'impianto di produzione del biometano e recupero energetico, ancora in fase progettuale, la cui ricaduta degli inquinanti è stata valutata nel Marzo del 2014 e composto da :

4. **biofiltro per l'abbattimento delle sostanze odorigene provenienti dal capannone di stoccaggio e preparazione F.O.R.S.U. (emissione E7);**
5. **impianto di cogenerazione alimentato a biometano (emissione E8);**

Le fasi di processo degli impianti "RU" – "RO" – "BI" sono quelle descritte nell'Autorizzazione Integrata Ambientale (AIA) con la quale gli stessi sono stati autorizzati, rilasciata dalla Regione Marche con D.D. n. 97/VAA del 21/10/2011 e s.m.i.

Le fasi di processo dell'impianto di produzione di biometano sono quelle descritte nella relazione tecnica del Marzo 2014.

### 3 Ricettori sensibili

I ricettori sensibili considerati nella presente valutazione sono i medesimi presi in considerazione nella precedente valutazione Prot. 127/14 VIATM: trattasi di due edifici residenziali vicini al perimetro della ASITE (Fig. 2), ritenuti maggiormente esposti all'attività dell'impianto sia per la loro vicinanza che esposizione alla circolazione delle masse d'aria nell'area considerata.

Per quanto riguarda il ricettore **RC2** si specifica che esso **si trova al di sotto della linea dell'orizzonte**, in direzione E-NE, **in quanto posto al di sotto di un leggero crinale che lo colloca "in ombra" rispetto alla posizione dell sorgenti.**

**Fig. 2 – Fotorilievo con indicazione dei ricettori sensibili.**

Date le caratteristiche di propagazione del modello diffusivo si è proceduto anche a determinare l'altitudine, rispetto al livello del mare, di ciascun ricettore e dello stabilimento in esame.

| Sito               | Ubicazione                        | Altitudine (m.s.l.m.) |
|--------------------|-----------------------------------|-----------------------|
| Stabilimento ASITE | /                                 | 181                   |
| RC1                | Edificio confinante lato Nord     | 191                   |
| RC2                | Edificio confinante lato Nord-Est | 171                   |

*Tab. 1 – Ricettori sensibili.*

#### 4 Modello di dispersione degli inquinanti

Il modello di simulazione utilizzato nella presente valutazione è lo **SCREEN3**, elaborato dalla US-EPA e basato sulle equazioni e sulle interazioni tra fattori relativi alla sorgente ed elementi meteorologici, descritte nel Volume II della User Guide dell'ISC (US-EPA) e nel Workbook of Atmospheric Dispersion Estimates (Turner): in esso **si assume che gli inquinanti non subiscono trasformazioni chimiche e che non avvengono processi di rimozione**, come deposizione secca o umida, **durante la dispersione in atmosfera**.

Il modello può svolgere un'analisi delle sorgenti puntuali, areali, volumetriche semplici e torce (*Flare*), effettuando stime degli effetti **Short Term** ed incorporando gli effetti del **Building Downwash** provocato dalla presenza di ostacoli (es: edifici) lungo il percorso del pennacchio, generando alte concentrazioni al suolo a causa delle turbolenze che si formano nella **Wake Region** (zona di turbolenza che si crea nella parte immediatamente posteriore ad un ostacolo causata dal flusso di aria passante sopra o intorno ad esso) o nella **Cavity Recirculation** (flusso vorticoso del vento che si genera immediatamente dopo un ostacolo).

Il modello fornece come output la concentrazione massima di ricaduta al suolo per diverse distanze orizzontali dalla sorgente calcolata nelle peggiori condizioni ipotizzabili (combinazione di velocità del vento e classe di stabilità atmosferica) o nelle condizioni reali, nel caso si disponga di dati meteorologici e classi di stabilità atmosferica.

SCREEN3 appartiene alla categoria dei modelli "Gaussian Plume" (modelli gaussiani) e consente, altresì, di stimare le ricadute di inquinanti in situazioni particolari quali:

- **Complex Terrain** (terreni complessi): situazione in cui l'altezza del terreno è maggiore di quella del camino;
- **Fumigation** (fumigazione): fenomeno che si genera dall'incontro tra il plume uscente dal camino ed un'area di turbolenza che ne determina la rapida dispersione al suolo generando

alte concentrazioni.

Il modello, inoltre, utilizza un algoritmo di calcolo (**Brode 2 Mixing Height - 1991**) che stima valori, per le situazioni più critiche, conservativi rispetto al modello EPA "ISCST3 model".

Per conoscere nel dettaglio l'equazione fondamentale che calcola le concentrazioni al livello del suolo e le equazioni subordinate e per approfondire la trattazione degli argomenti sopra esposti, si rimanda alla consultazione del manuale tecnico *"US-EPA SCREEN3 Model User's Guide"*.

Al par. 5.3.1 sono indicati i parametri con cui il modello è stato impostato per effettuare la presente valutazione.

## 5 Previsione dell'incremento di inquinanti in atmosfera

Nell'area circostante il sito della ASITE non sono presenti attività industriali o commerciali che possano generare emissioni in atmosfera, legate anche alla circolazione di traffico locale. L'urbanizzazione della zona, riconducibile ad edifici rurali sparsi tipici di abitazioni poste nelle campagne delle colline marchigiane lasciano presupporre una buona qualità dell'aria con livelli di concentrazione degli inquinanti atmosferici primari (Polveri, CO, NO<sub>x</sub>, SO<sub>2</sub>, NMHC) per la maggior parte del tempo al di sotto dei limiti di qualità dell'aria stabiliti dalla vigente normativa, ma con possibilità di superamenti dei limiti in condizioni meteorologiche particolarmente sfavorevoli.

### 5.1 Individuazione e significatività delle sorgenti di emissione

Alla luce delle modalità operative di trattamento dei rifiuti, sono state individuate le seguenti sorgenti di inquinamento atmosferico:

1. Scarico fossa impianto selezione RU: emissione di particolato;
2. Biofiltro sezione compostaggio RU: composti tipici della fermentazione anaerobica della sostanza organica (NH<sub>3</sub>, H<sub>2</sub>S);
3. I° gruppo elettrogeno: prodotti della combustione del biogas (Polveri, HCl, COT, HF, NO<sub>x</sub>, CO, SO<sub>x</sub>);
4. II° gruppo elettrogeno: prodotti della combustione del biogas (Polveri, HCl, COT, HF, NO<sub>x</sub>, CO, SO<sub>x</sub>);
5. Biofiltro compostaggio rifiuti organici: composti tipici della fermentazione anaerobica della sostanza organica (NH<sub>3</sub>, H<sub>2</sub>S);
6. Biofiltro lavorazione FORSU: composti tipici della fermentazione anaerobica della sostanza organica (NH<sub>3</sub>, H<sub>2</sub>S);
7. III° gruppo elettrogeno: prodotti della combustione del biogas (Polveri, HCl, COT, HF, NO<sub>x</sub>, CO, SO<sub>x</sub>).

I tempi delle lavorazioni e le quantità orarie di riferimento (materiale lavorato) previsti sono i seguenti:

| Sorgente                                | Attività   | Durata attività | Quantità |
|---|--|-----------------|----------|
| Scarico fossa impianto selezione RU     | Aspirazione dell'aria nella zona di della selezione primaria e stoccaggio.   | 12 h/g          | /        |
| Biofiltro compostaggio RU               | Depurazione del flusso d'aria convogliato dal sistema di aspirazione del capannone della sezione compostaggio RU               | 24 h/g          | /        |
| I° Gruppo elettrogeno                   | Combustione del biogas e produzione di energia elettrica e termica utilizzate nello stabilimento                               | 24 h/g          | /        |
| II° Gruppo elettrogeno                  | Combustione del biogas e produzione di energia elettrica e termica utilizzate nello stabilimento                               | 24 h/g          | /        |
| Biofiltro compostaggio rifiuti organici | Depurazione del flusso d'aria convogliato dal sistema di aspirazione del capannone della sezione compostaggio rifiuti organici | 24 h/g          | /        |
| Biofiltro lavorazione FORSU             | Depurazione del flusso d'aria convogliato dal sistema di aspirazione del capannone di stoccaggio della FORSU                   | 24 h/g          | /        |
| III° gruppo elettrogeno                 | Combustione del biogas e produzione di energia elettrica e termica utilizzate nello stabilimento                               | 24 h/g          | /        |

**Tab. 2** – Sorgenti significative di emissione individuate.

## 5.2 Definizione dei fattori di emissione

Al fine di poter effettuare una stima degli impatti prodotti dall'attività in esame è necessario, per ciascuna delle fasi, delle lavorazioni, delle tipologie di macchinario e delle rispettive modalità operative, poter disporre di specifici fattori di emissione.

Tali dati possono, in alcuni casi, essere determinati da un'analisi bibliografica, in altri, dai database disponibili o dai risultati d'indagini specifiche effettuate in situazioni simili. Deve essere sottolineato che i fattori di emissione, qualora sufficientemente attendibili, sono utilizzati con lo scopo di caratterizzare le sorgenti stesse e determinarne, in prima approssimazione, le dimensioni degli ambiti d'impatto potenziale.

L'individuazione delle sorgenti e la determinazione dei fattori d'emissione ad esse legati, richiede un'analisi dettagliata del processo di lavorazione e dei mezzi utilizzati, secondo quanto descritto al par. 5.1. Di seguito sono riportate le tipologie di sorgenti ritenute significative, per le quali è stato possibile effettuare delle ipotesi sulla definizione dei fattori di emissione specifici.

| Sorgente   | Descrizione emissione   | Tipo di sorgente     |
|--|---|----------------------|
| Aspirazione scarico fossa e selezione (filtro a maniche) | <ul style="list-style-type: none"> <li>▪ <u>Emissione convogliata</u> di materiale particolato proveniente dalle operazioni di apertura dei sacchi, selezione primaria dei rifiuti e stoccaggio in fossa</li> </ul> | <b>PUNTUALE (E1)</b> |

|              |  |                      |
|--------------|--|----------------------|
| Biofiltro    | ▪ <u>Emissione convogliata</u> di NH <sub>3</sub> e H <sub>2</sub> S provenienti dai processi di compostaggio dei rifiuti solidi all'interno del capannone   | <b>AREALE (E3)</b>   |
| Cogeneratore | ▪ <u>Emissione convogliata</u> dei fumi di combustione   | <b>PUNTUALE (E4)</b> |
| Cogeneratore | ▪ <u>Emissione convogliata</u> dei fumi di combustione   | <b>PUNTUALE (E5)</b> |
| Biofiltro    | ▪ <u>Emissione convogliata</u> di NH <sub>3</sub> e H <sub>2</sub> S provenienti dai processi di compostaggio dei rifiuti organici all'interno del capannone | <b>AREALE (E6)</b>   |
| Biofiltro    | ▪ <u>Emissione convogliata</u> di NH <sub>3</sub> e H <sub>2</sub> S provenienti dai processi di lavorazione della FORSU                                     | <b>AREALE (E7)</b>   |
| Cogeneratore | ▪ <u>Emissione convogliata</u> dei fumi di combustione   | <b>PUNTUALE (E8)</b> |

**Tab. 3** – Definizione delle sorgenti.

### 5.2.1 Fattori di emissione per il “Filtro a maniche”

Gli “*Emission Rate*” in input al modello di calcolo sono stati calcolati a partire dai valori della concentrazione di Polveri Totali autorizzata nel D.D. n. 97/VAA del 21/10/2011, considerando un rapporto PM<sub>10</sub>/PTS pari a 0,55 così come riportato nel documento dell'Organizzazione Mondiale della Sanità “*Health impact assessment of air pollution in the eight major Italian cities*”

| Parametro | Concentrazione (mg/Nm <sup>3</sup> ) | Flusso di massa (kg/h) | Emission Rate (g/s)                       |
|-----------|--------------------------------------|------------------------|---|
| Polveri   | 10,0                                 | 0,2                    | 3,06x10 <sup>-2</sup> (PM <sub>10</sub> ) |

**Tab. 4** – Emission Rate utilizzati nel modello di simulazione (E1).

### 5.2.2 Fattori di emissione per i “Biofiltri”

Ai biofiltri viene convogliata l'aria di ricambio dei capannoni in cui vengono compostati i rifiuti urbani, i rifiuti organici e la FORSU tramite idonei sistemi di aspirazione. La finalità di ciascuno dei biofiltri è quella di abbattere i composti che si producono nelle fasi di decomposizione anaerobica dei substrati organici trattati. Dopo il passaggio sui biofiltri (E3 – E6 – E7) le esalazioni vengono espulse in atmosfera.

Gli “*Emission Rate*” in input al modello di calcolo, per le sole emissioni E3 ed E6 in quanto per E7 la valutazione è stata condotta nel Marzo 2014, sono stati calcolati a partire dai valori delle concentrazioni autorizzate e riportate nell'AIA.

| E3 – BIOFILTRO SEZIONE COMPOSTAGGIO RU |                |                 |               |
|--|----------------|-----------------|---------------|
| Parametro                              | Concentrazione | Flusso di massa | Emission Rate |

|                  | (mg/Nm <sup>3</sup> ) | (kg/h) | (g/s*m <sup>2</sup> )  |
|------------------|-----------------------|--------|------------------------|
| NH <sub>3</sub>  | 20,0                  | 1,17   | 8,11x10 <sup>-4</sup>  |
| H <sub>2</sub> S | 4,5                   | 0,26   | 1,82 x10 <sup>-4</sup> |

*Tab. 5 – “Emission Rate” utilizzati nel modello di simulazione (E3).*

### 5.2.3 Fattori di emissione per i “fumi di combustione del cogeneratore”

Anche per questa sorgente, con riferimento alle sole emissioni E4 ed E5, in quanto E8 è stata valutata nella relazione del Marzo 2014, gli “Emission Rate” sono stati definiti a partire dai valori di concentrazione di inquinanti autorizzati con l’AIA.

Per quanto riguarda la stima dell’emissione di NO<sub>2</sub> è stata considerata una quantità pari al 5% del totale degli NO<sub>x</sub>, come proposto dagli enti ed agenzie ambientali italiane (ARPA Veneto – Glossario dei rischi ambientali, ARPA Emilia Romagna – Rete di Monitoraggio della qualità dell’aria Report 2005).

Per quanto concerne il parametro PM<sub>10</sub> esso è stato determinato considerando un rapporto PM<sub>10</sub>/PTS pari a 0,55 secondo quanto riportato al par. 5.2.1.

*Tab. 7 – Emission Rate utilizzati nel modello di simulazione (gruppi elettrogeni).*

### 5.3 Simulazione di ricaduta degli inquinanti

La previsione dell'impatto sulla qualità dell'aria dovuto all'attività in esame necessita, oltreché della caratterizzazione delle sorgenti, anche della definizione di scenari di medio e massimo impatto. Gli scenari considerati sono di seguito descritti.

Al fine di calcolare l'impatto dovuto alle sostanze rilasciate durante le fasi lavorative sono state rilevate le posizioni relative "sorgente - ricettore" sia in termini di distanza che di dislivello. In Fig. 3 sono indicate le sorgenti di emissione individuate presso lo stabilimento.

**Fig. 3** – Localizzazione sorgenti.

Per valutare gli impatti delle singole sorgenti sono state rilevate le quote e le distanze dei ricettori sensibili dalle sorgenti. Le distanze sorgente-ricettore (per le sole E1 – E3 – E4 – E5 – E6 in quanto E7 ed E8 sono stati valutati nella precedente relazione) sono riportati nella tabella che segue:

| Ricettore | Distanza da E1<br>(m) | Distanza da E3<br>(m) | Distanza da E4<br>(m) | Distanza da E5<br>(m) | Distanza da E6<br>(m) |
|-----------|-----------------------|-----------------------|-----------------------|-----------------------|-----------------------|
| RC1       | 240                   | 165                   | 271                   | 260                   | 277                   |
| RC2       | 185                   | 230                   | 205                   | 220                   | 140                   |

**Tab. 8** – Distanze e dislivelli sorgenti-ricettori.

### 5.3.1 Impostazione del modello di simulazione

Per il calcolo delle ricadute degli inquinanti sono stati utilizzati i seguenti criteri:

- Per gli stessi inquinanti emessi da più fasi/attività identificabili con la medesima sorgente, l'Emission Rate in input al modello è costituito dalla somma dei singoli Emission Rate individuati per ciascun inquinante;
- Tutte le simulazioni sono state effettuate considerando il massimo livello di emissione oraria considerando le varie fasi di lavorazione continuative e contemporanee per tutto il tempo;
- Le concentrazioni di massima ricaduta al suolo sono state stimate nelle condizioni di dispersione più sfavorevoli per tutte le classi di stabilità atmosferica (classi di Pasquill) e alla luce della morfologia della zona;
- Il modello è stato impostato per il calcolo, lungo la direttrice scelta, del massimo inquinamento possibile per le diverse condizioni atmosferiche (es: calcolo della velocità del vento in grado di provocare la massima ricaduta al suolo) e tali risultanze sono state cautelativamente estese a tutte le direzioni;
- Le condizioni operative scelte in maniera peggiorativa rispetto alla realtà potranno verificarsi solamente per limitati periodi di tempo.

I dati di input al modello relativamente alle opzioni possibili sono stati i seguenti:

| Parametro                              | u.m.                  | E1                   | E3                        | E4                    | E5                     | E6                                      |

| <b>Conservative Brode 2 Mixing Height Option</b> | / | Yes | Yes | Yes | Yes | Yes |

**Tab. 9 – Parametri di Input del modello.**

Per quanto concerne le parametrizzazioni impiegate per la simulazione, al fine di avere una valutazione nelle condizioni più sfavorevoli, i calcoli sono stati effettuati attivando le opzioni:

- “Worst Case Meteorological Condition”;
- “Conservative Brode 2 Mixing Height Option”.

La prima condizione fa sì che il modello di simulazione individui le condizioni di stabilità atmosferica e di velocità del vento in grado di provocare la massima concentrazione di ricaduta al suolo, per le diverse distanze, degli inquinanti emessi dalle sorgenti considerate.

Con la seconda, l'altezza dello strato di rimescolamento viene calcolata sui livelli minimi in relazione alla velocità del vento ed alla stabilità atmosferica considerate. L'impiego di tale opzione porta a stime conservative rispetto a modelli simili quali “ISCST US-EPA Model”.

L'opzione “RURAL” è stata scelta alla luce sia della natura del territorio sia perché la situazione che interessa prevalentemente monitorare è quella relativa all'area circostante lo stabilimento.

Nell'allegato A alla presente valutazione sono riportati i risultati di tutte le simulazioni di ricaduta degli inquinanti emessi per i diversi scenari ipotizzati.

Le tabelle riportano, per ogni situazione simulata, i livelli di massima concentrazione di ricaduta al suolo attesi per le condizioni scelte alle diverse distanze dalle sorgenti, nonché le condizioni meteorologiche in cui le stesse si verificano.

### 5.3.2 Risultati della simulazione

Nei seguenti paragrafi si riportano i riepiloghi, a partire dalle schede di ricaduta elaborate per ciascun inquinante emesso dalle sorgenti per ciascuna classe di stabilità atmosferica, delle concentrazioni massime di ricaduta al suolo.

#### 5.3.2.1 $PM_{10}$

Tab. 12 – Ricaduta  $PM_{10}$  da E5.

Al fine di valutare l'impatto cumulativo, si è proceduto al calcolo della sommatoria delle concentrazioni di ricaduta presso ciascun ricettore. Alla luce del fatto che il modello restituisce la concentrazione massima di ricaduta nell'ora, visti i tempi di funzionamento delle varie sorgenti sulla base dei quali è stato calcolato l'Emission Rate e la media giornaliera sulla quale è basato il

limite per la qualità dell'aria, è stato considerato:

- per il contributo delle **polveri provenienti dal filtro a maniche della fossa RU** una concentrazione media di ricaduta pari ad 1/2 di quella calcolata (tempo di funzionamento medio pari a 12 h/g);

Per quanto riguarda la sorgente E8, si è fatto riferimento ai dati riportati nella valutazione di ricaduta Prot. 127/14 VIATM del 27/03/2014.

| Ricettore | Contributo ricaduta ( $\mu\text{g}/\text{m}^3$ ) |                             |                              |                               | Conc. massima ricaduta ( $\mu\text{g}/\text{m}^3$ ) |

*Tab. 36 – Ricaduta NO<sub>2</sub> da E5.*

Al fine di valutare l'impatto cumulativo, alla luce del fatto che il modello restituisce la concentrazione massima di ricaduta nell'ora, si è proceduto al calcolo della sommatoria delle concentrazioni di ricaduta presso ciascun ricettore. Nella seguente tabella sono riportati i contributi di SO<sub>x</sub> provenienti da tutte le sorgenti identificate.

Per quanto riguarda la sorgente E8, si è fatto riferimento ai dati riportati nella valutazione di ricaduta Prot. 127/14 VIATM del 27/03/2014.

| Ricettore | Contributo ricaduta (µg/m <sup>3</sup> ) |                              |                               | Conc. massima ricaduta (µg/m <sup>3</sup> ) |
|-----------|--|------------------------------|-------------------------------|---|

*Tab. 37 – Ricaduta cumulativa SO<sub>x</sub>.*

## 6 Confronto con i limiti di riferimento

La normativa di riferimento in tema di controllo della qualità dell'aria è costituita dal **D.Lgs. 155/2010** – “Attuazione della Direttiva 2008/50/CE relativa alla qualità dell'aria ambiente e per un'aria più pulita in Europa” che, all'art. 21 c. 1 lett. q, ha abrogato il D.M 60/2002 (Recepimento della Direttiva 1999/30/CE del Consiglio del 22 Aprile 1999 concernente i valori limite di qualità dell'aria ambiente per il Biossido di Zolfo, il Biossido di Azoto, gli Ossidi di Azoto, le particelle e il Piombo e della direttiva 2000/69/CE relativa ai valori limite di qualità dell'aria ambiente per il Benzene ed il Monossido di Carbonio) che stabiliva in precedenza i valori limite per la qualità dell'aria.

Il D.Lgs. 155/2010 stabilisce, all'allegato XI, i valori limite per NO<sub>2</sub>, CO, PM<sub>10</sub>, Pb e all'allegato XIII, i valori obiettivo per As, Cd e Ni nell'aria.

| Inquinante       | Valore limite | Valore obiettivo | u.m               | Periodo di mediazione |
|------------------|---------------|------------------|-------------------|-----------------------|
| PM <sub>10</sub> | 50            | /                | µg/m <sup>3</sup> | 24 h                  |
| CO               | 10            | /                | mg/m <sup>3</sup> | 8 h                   |
| NO <sub>2</sub>  | 200           | /                | µg/m <sup>3</sup> | 1 h                   |

**Tab. 38** – Valori limite e obiettivo per la qualità dell'aria.

In relazione alla ricaduta di HCl, HF, NH<sub>3</sub>, H<sub>2</sub>S e SO<sub>2</sub> non sono stati stabiliti limiti di concentrazione per la qualità dell'aria. Per l'impatto di tali inquinanti si è fatto riferimento ai livelli di tossicità TLV (*Threshold Limit Value*), nell'elaborazione TWA (*Time Weight Average* – media ponderata per un periodo di 8 ore) e in subordine nella forma STEL (*Short Term Exposure Limit* – valore massimo consentito per esposizioni <15'), stabiliti dall'allegato XXXVIII al D.Lgs. 81/08, laddove disponibili, altrimenti dalla ACGIH (*American Conference of Governmental Industrial Hygienists*).

| Inquinante       | TLV mg/m <sup>3</sup> | Elaborazione | Fonte                     |
|------------------|-----------------------|--------------|---------------------------|
| HCl              | 2,9                   | TLV – TWA    | D.Lgs. 81/08 All. XXXVIII |
| HF               | 1,5                   | TLV – TWA    | D.Lgs. 81/08 All. XXXVIII |
| NH <sub>3</sub>  | 14,0                  | TLV – TWA    | D.Lgs. 81/08 All. XXXVIII |
| H <sub>2</sub> S | 7,0                   | TLV – TWA    | D.Lgs. 81/08 All. XXXVIII |
| SO <sub>2</sub>  | 0,66                  | TLV – STEL   | ACGIH                     |

**Tab. 39** – TLV di alcuni inquinanti.

Per quanto concerne gli scenari ipotizzati e descritti nei precedenti paragrafi è possibile prendere in considerazione, **come valori di assoluta cautela, i dati di concentrazione massima di**

**ricaduta al suolo sul breve periodo** relativi alle simulazioni riportate nell'allegato A.

Dall'esame dei dati si evince che un'ampissima porzione del territorio interessato dall'attività della ASITE, che comprende tutti i recettori sensibili e la popolazione interessata, risulta essere esposta ad un incremento massimo potenziale del livello di inquinanti atmosferici molto modesto, con valori sempre al di sotto dei valori limite imposti.

Se si considera poi che:

- 1) Le concentrazioni di ricaduta calcolate si riferiscono a condizioni di funzionamento in contemporanea di tutti gli impianti ed alla massima potenzialità;
  - 2) La ricaduta al suolo degli inquinanti è stata calcolata come valore massimo nell'ora;
  - 3) Nella simulazione è stata impostata una velocità del vento pari ad 1,0 m/sec (velocità raccomandata dall'US-EPA come quella per la quale si verificano le peggiori condizioni di ricaduta al suolo degli inquinanti) sicuramente penalizzante ai fini del presente studio;
- è possibile affermare che lo scenario di ricaduta degli inquinanti presso i ricettori sensibili considerati sarà sicuramente migliore rispetto a quello valutato in via previsionale.

## 7 Conclusioni

Per avere un quadro più generale e realistico della situazione, è necessario considerare quanto segue:

- **I valori di concentrazione massimi possibili di inquinanti, attesi alla quota dei recettori più esposti e più prossimi**, si verificano, come valutato dal modello, per condizioni di neutralità atmosferica nel 8,7% dei casi, leggera instabilità atmosferica nel 5,7% dei casi e leggera stabilità atmosferica nel 1,75% dei casi riconducibili alle classi di stabilità di Pasquill D, C ed E rispettivamente. La classe D si verifica prevalentemente nelle ore notturne o diurne in presenza di scarsa radiazione solare ed elevata ventosità, la classe C si può verificare nelle ore diurne in condizioni di forte irradiazione solare ed elevata ventosità o scarsa radiazione solare e contenuta ventosità mentre la classe E può verificarsi solamente nelle ore notturne. Nella maggioranza dei casi, nell'area interessata, vi sarà pertanto **condizione meteorologica diversa da quella di massima ricaduta**;
- Le ipotesi di calcolo partono da dati di massima emissione possibile nelle condizioni "Worst Case Meteorological Condition";
- Nelle equazioni del modello si assume che **gli inquinanti non subiscano trasformazioni chimiche e non avvengono processi di rimozione durante la dispersione in atmosfera**;
- La distribuzione spaziale delle ricadute, **calcolate puntualmente e nel loro valore massimo possibile**, nella realtà interesserà vari settori di area con una variabilità sia nell'arco della giornata (variabilità dei regimi anemometrici causata dall'orografia dell'area), sia nelle diverse stagioni dell'anno (variabilità dell'intensità della radiazione solare incidente) che garantirà una dispersione su più settori degli inquinanti e livelli puntuali di concentrazione, sia su base giornaliera che oraria, sensibilmente più bassi (es: **i ricettori sono interessati solamente da masse d'aria provenienti dai quadranti sud-occidentali**) . Inoltre **tali incrementi potranno, in relazione alle diverse condizioni meteorologiche, verificarsi con bassa frequenza ed interessare porzioni di territorio limitate**: in sostanza la ricaduta non interesserà sempre tutti i recettori ma solo quelli esposti riducendo ulteriormente il tempo di esposizione dei singoli recettori all'impatto dell'impianto.

Pertanto, tenendo conto delle valutazioni e delle considerazioni fatte, si ritiene sia possibile concludere che, **nelle condizioni operative previste, anche ipotizzando che l'attività si svolga sempre al massimo della potenzialità possibile:**

1. **gli incrementi massimi di concentrazione di  $PM_{10}$**  nell'aria dovuti all'attività in esame, referiti alla media sulle 24h per singolo settore di territorio, sono stimati **non superiori a 6,3  $\mu g/m^3$**  per il ricettore RC1 e **5,0  $\mu g/m^3$**  per il ricettore RC2 **corrispondenti al 12,5% e 10,1% rispettivamente del valore limite giornaliero** fissato dal D.Lgs. 155/2010;
2. **gli incrementi massimi di concentrazione di  $NH_3$**  nell'aria dovuti all'attività in esame, referiti alla media oraria per singolo settore di territorio, sono stimati **non superiori a 0,68  $mg/m^3$**  per il ricettore RC1 e **0,76  $mg/m^3$**  per il ricettore RC2, pari a **4,9% e 5,4% rispettivamente** del TLV-TWA stabilito dall'All. XXXVIII al D.Lgs. 81/2008;
3. **gli incrementi massimi di concentrazione di  $H_2S$**  nell'aria dovuti all'attività in esame, referiti alla media oraria per singolo settore di territorio, sono stimati **non superiori a 0,22  $mg/m^3$**  pari a **3,2%** del TLV-TWA stabilito dall'All. XXXVIII al D.Lgs. 81/2008;
4. **gli incrementi massimi di concentrazione di  $HCl$**  nell'aria dovuti all'attività in esame, referiti alla media oraria per singolo settore di territorio, sono stimati **non superiori a 5,9  $\mu g/m^3$**  per il ricettore RC1 e **4,2  $\mu g/m^3$**  per il ricettore RC2, pari a **0,07% e 0,05% rispettivamente** del TLV-TWA stabilito dall'All. XXXVIII al D.Lgs. 81/2008;
5. **gli incrementi massimi di concentrazione di composti organici (espressi come COT)** nell'aria dovuti all'attività in esame, referiti alla media oraria per singolo settore di territorio, sono stimati **non superiori a 0,089  $mg/m^3$**  per il ricettore RC1 e **0,063  $mg/m^3$**  per il ricettore RC2;
6. **gli incrementi massimi di concentrazione di  $HF$**  nell'aria dovuti all'attività in esame, referiti alla media oraria per singolo settore di territorio, sono stimati **non superiori 1,2  $\mu g/m^3$**  per il ricettore RC1 e **0,8  $\mu g/m^3$**  per il ricettore RC2, pari a **0,08% e 0,05% rispettivamente** del TLV-TWA stabilito dall'All. XXXVIII al D.Lgs. 81/2008;
7. **gli incrementi massimi di concentrazione di  $NO_2$**  nell'aria dovuti all'attività in esame, referiti alla media oraria per singolo settore di territorio, sono stimati **non superiori 13,3  $\mu g/m^3$**  per il ricettore RC1 e **9,5  $\mu g/m^3$**  per il ricettore RC2 **corrispondenti a 6,7% e 4,8% rispettivamente del valore limite orario** fissato dalla vigente normativa;
8. **gli incrementi massimi di concentrazione di  $CO$**  nell'aria dovuti all'attività in esame, referiti alla media oraria per singolo settore di territorio, sono stimati **non superiori a 0,29  $mg/m^3$**  per il ricettore RC1 e **0,21  $mg/m^3$**  per il ricettore RC2 **corrispondenti a 3,0% e**

2,1% rispettivamente del valore limite sulle 8 h fissato dalla vigente normativa;

9. **gli incrementi massimi di concentrazione di SO<sub>x</sub>** nell'aria dovuti all'attività in esame, riferiti alla media oraria per singolo settore di territorio, sono stimati **non superiori 20,5 µg/m<sup>3</sup>** per il ricettore RC1 e **20,9 µg/m<sup>3</sup>** per il ricettore RC2, pari a **3,1% e 3,2% rispettivamente** del TLV-TWA stabilito dall'ACGIH riferito alla SO<sub>2</sub>;

Alla luce di tutto quanto sopra esposto è pertanto possibile ritenere che **le concentrazioni di ricaduta degli inquinanti atmosferici** emessi dall'attività oggetto del presente studio, considerate anche le modalità ed i tempi di lavorazione previsti e la limitatezza spaziale del territorio interessato dal fenomeno, **sono da ritenersi tali da non modificare significativamente lo stato della qualità dell'aria della zona e garantire il mantenimento del rispetto dei valori limite** imposti dal D.Lgs. 155/2010.

## 8 Allegati – Schede di ricaduta degli inquinanti

Si allegano alla presente valutazione n° 114 schede di simulazione di massima ricaduta degli inquinanti.

## 1 Premessa

Nella presente Relazione Tecnica è riportata una **Valutazione Previsionale dell'impatto sull'atmosfera** dovuto alle emissioni di sostanze inquinanti che si sviluppano nelle condizioni di normale esercizio dell'attività presso l'impianto per la digestione anaerobica dei rifiuti della **"ASITE – Fermo Ambiente Servizi Impianti Tecnologici Energia"** sito in C.da San Biagio nel **Comune di Fermo (FM)**.

Lo studio è teso a verificare il rispetto dei limiti di concentrazione degli inquinanti nell'area prossima al sito in relazione alle emissioni in atmosfera convogliate attraverso:

1. **E1 – Biofiltro per l'abbattimento delle sostanze odorigene provenienti dal capannone di stoccaggio e preparazione F.O.R.S.U.;**
2. **E2 – Impianto di cogenerazione alimentato a biometano;**

Le valutazioni sono state condotte mediante simulazione effettuata, a partire dai dati di progetto, secondo la metodologia di seguito descritta:

1. Per caratterizzare le emissioni derivanti dai processi di trattamento dei materiali sono stati impiegati specifici fattori di emissione per le diverse attività esaminate, riportati e descritti nei paragrafi che seguono;
2. Per la simulazione di ricaduta al suolo degli inquinanti atmosferici è stato impiegato il modello di dispersione **"Gaussian Plume" SCREEN3 Vers. 96043** elaborato dalla **US-EPA** (United States - Environmental Protection Agency);
3. Al fine di simulare cautelativamente le situazioni più acute di impatto, sono state stimate le ricadute al suolo massime, in modalità **"Short Term"** (concentrazione media su 1 – 24h), degli inquinanti.

## 2 Dati di progetto

### 2.1 Area dell'insediamento

Il sito della della ASITE, sito in Loc. San Biagio nel Comune di Fermo, si estende su una superficie di oltre 10.000 m<sup>2</sup>: in una porzione di questa si intende realizzare l'impianto di digestione anaerobica dei rifiuti di origine organica.

L'area circostante lo stabilimento è a carattere tipicamente rurale con presenza di case sparse. In Fig. 1 è riportato un rilievo fotografico della zona interessata con, evidenziata, l'area interessata dal nuovo intervento dello stabilimento della ASITE

*Fig. 1 – Fotorilievo dell'area della ASITE*

### 2.2 Descrizione dell'attività produttiva

La ASITE intende realizzare un impianto di digestione anaerobica per la produzione di biometano da immettere nella rete di distribuzione del gas a partire dalla FORSU proveniente dalla raccolta dei rifiuti sul territorio. Il ciclo di funzionamento si compone delle seguenti fasi:

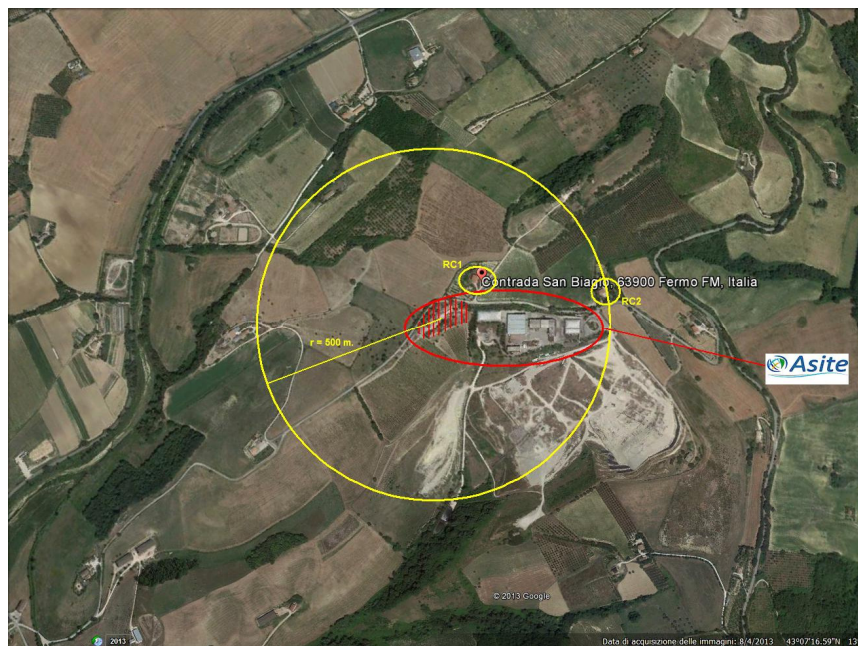

1. **Ricevimento e stoccaggio della FORSU:** il rifiuto viene scaricato e stoccato all'interno di un capannone appositamente progettato;
2. **Pretrattamento FORSU:** all'interno del capannone di stoccaggio vengono effettuate le

operazioni di pretrattamento che servono ad eliminare le “impurezze” dalla biomassa consentendo di inviare al digestore un materiale effettivamente putrescibile in grado di produrre metano. Vengono infatti eliminate le parti solide grossolane che potrebbero intasare la linea, le parti leggere costituite dai sacchetti di plastica ed il materiale solido fine (es. sabbie) che andrebbero a depositarsi in fondo al digestore;

3. **Digestione anaerobica:** la FORSU pretrattata viene pompata all'interno di un primo serbatoio che costituisce il polmone del digestore dove hanno luogo le prime fasi di idrolisi e acidificazione del substrato organico. Il materiale in uscita dal serbatoio di idrolisi viene pompato in due reattori dove avvengono le fasi di acetogenesi e metanogenesi ad opera di specifici ceppi di batteri anaerobi che utilizzano la sostanza organica come fonte di energia per il proprio metabolismo effettuato in assenza di ossigeno (fermentazione anaerobica). All'interno dei due reattori la biomassa viene continuamente miscelata al fine di favorire il contatto tra batteri e substrato, l'omogeneizzazione della temperatura, ottimizzare il rilascio del biogas, evitare la decantazione delle frazioni più pesanti ed evitare invece che quella più leggera si addensasse nella parte superiore andando a costituire una sorta di tappo che possa ostacolare la formazione ed il rilascio del metano.
4. **Stoccaggio del biogas:** il biogas prodotto all'interno del digestore si accumula nella parte superiore (cupola) che, in molti casi, funge da contenitore di stoccaggio. Nel caso specifico è prevista invece l'installazione di un gasometro appositamente deputato allo stoccaggio del biogas prodotto consentendo così di garantire continuità di alimentazione ai sistemi di depurazione ed evitare che nei casi di manutenzione del cogeneratore si debba inviare il biogas in torcia perdendo il contenuto energetico dello stesso;
5. **Cogenerazione:** parte del biogas prodotto viene inviato all'impianto di cogenerazione per la produzione di energia elettrica e termica. Entrambi i vettori energetici vengono riutilizzati nell'impianto per garantire il funzionamento di tutti i macchinari (energia elettrica) ed il mantenimento delle condizioni termiche dei reattori che devono essere riscaldati (calore);
6. **Produzione di Biometano:** il biogas prodotto viene sottoposto a delle operazioni di depurazione (*up grading*) per l'eliminazione di contaminanti ed impurità in esso contenute (es: vapore acqueo, materiale particolato, CO<sub>2</sub>, SO<sub>2</sub>, NH<sub>3</sub>, silossani) al fine di rientrare nei parametri previsti per poter essere classificato come biometano ed essere idoneo agli impieghi previsti dal D.M. 17/12/2013.

### 3 Ricettori sensibili

Alla luce della morfologia dell'area, sensibilmente caratterizzata da versanti collinari con cambi di pendenze nelle 4 direzioni cardinali, sono stati presi in considerazione i ricettori sensibili ricadenti all'interno di un raggio di 500 m. dal punto dove è prevista la collocazione delle sorgenti all'interno dell'impianto (Fig. 2). Nel caso specifico sono individuati due edifici residenziali vicini al perimetro della ASITE, ritenuti maggiormente esposti all'attività dell'impianto sia per la loro vicinanza che esposizione alla circolazione delle masse d'aria nell'area considerata. Per quanto riguarda il ricettore **RC2** si specifica che esso **si trova al di sotto della linea dell'orizzonte**, in direzione E-NE, in quanto posto al di sotto di un leggero crinale che lo colloca "in ombra" rispetto alla posizione delle sorgenti.

*Fig. 2 – Fotorilievo con indicazione dei ricettori sensibili.*

Date le caratteristiche di propagazione del modello diffusivo si è proceduto anche a determinare l'altitudine, rispetto al livello del mare, di ciascun ricettore e dello stabilimento in esame.

| Sito               | Ubicazione                        | Altitudine (m.s.l.m.) |
|--------------------|-----------------------------------|-----------------------|
| Stabilimento ASITE | /                                 | 181                   |
| RC1                | Edificio confinante lato Nord     | 191                   |
| RC2                | Edificio confinante lato Nord-Est | 171                   |

*Tab. 1 – Ricettori sensibili.*

## 4 Modello di dispersione degli inquinanti

Il modello di simulazione utilizzato nella presente valutazione è lo **SCREEN3**, elaborato dalla US-EPA e basato sulle equazioni e sulle interazioni tra fattori relativi alla sorgente ed elementi meteorologici, descritte nel Volume II della User Guide dell'ISC (US-EPA) e nel Workbook of Atmospheric Dispersion Estimates (Turner): in esso **si assume che gli inquinanti non subiscono trasformazioni chimiche e che non avvengono processi di rimozione**, come deposizione secca o umida, **durante la dispersione in atmosfera**.

Il modello può svolgere un'analisi delle sorgenti puntuali, areali, volumetriche semplici e torce (*Flare*), effettuando stime degli effetti **Short Term** ed incorporando gli effetti del **Building Downwash** provocato dalla presenza di ostacoli (es: edifici) lungo il percorso del pennacchio, generando alte concentrazioni al suolo a causa delle turbolenze che si formano nella **Wake Region** (zona di turbolenza che si crea nella parte immediatamente posteriore ad un ostacolo causata dal flusso di aria passante sopra o intorno ad esso) o nella **Cavity Recirculation** (flusso vorticoso del vento che si genera immediatamente dopo un ostacolo).

Il modello fornisce come output la concentrazione massima di ricaduta al suolo per diverse distanze orizzontali dalla sorgente calcolata nelle peggiori condizioni ipotizzabili (combinazione di velocità del vento e classe di stabilità atmosferica) o nelle condizioni reali, nel caso si disponga di dati meteorologici e classi di stabilità atmosferica.

SCREEN3 appartiene alla categoria dei modelli "Gaussian Plume" (modelli gaussiani) e consente, altresì, di stimare le ricadute di inquinanti in situazioni particolari quali:

- **Complex Terrain** (terreni complessi): situazione in cui l'altezza del terreno è maggiore di quella del camino;
- **Fumigation** (fumigazione): fenomeno che si genera dall'incontro tra il plume uscente dal camino ed un'area di turbolenza che ne determina la rapida dispersione al suolo generando alte concentrazioni.

Il modello, inoltre, utilizza un algoritmo di calcolo (**Brode 2 Mixing Height - 1991**) che stima valori, per le situazioni più critiche, conservativi rispetto al modello EPA "ISCST3 model".

Per conoscere nel dettaglio l'equazione fondamentale che calcola le concentrazioni al livello del suolo e le equazioni subordinate e per approfondire la trattazione degli argomenti sopra esposti, si rimanda alla consultazione del manuale tecnico "*US-EPA SCREEN3 Model User's Guide*".

Al par. 5.3.1 sono indicati i parametri con cui il modello è stato impostato per effettuare la presente valutazione.

## 5 Previsione dell'incremento di inquinanti in atmosfera

Nell'area circostante il sito della ASITE non sono presenti attività industriali o commerciali che possano generare emissioni in atmosfera, legate anche alla circolazione di traffico locale. L'urbanizzazione della zona, riconducibile ad edifici rurali sparsi tipici di abitazioni poste nelle campagne delle colline marchigiane lasciano presupporre una buona qualità dell'aria con livelli di concentrazione degli inquinanti atmosferici primari (Polveri, CO, NO<sub>x</sub>, SO<sub>2</sub>, NMHC) per la maggior parte del tempo al di sotto dei limiti di qualità dell'aria stabiliti dalla vigente normativa, ma con possibilità di superamenti dei limiti in condizioni meteorologiche particolarmente sfavorevoli.

### 5.1 Individuazione e significatività delle sorgenti di emissione

Alla luce delle modalità operative di produzione del biometano, sono state individuate le seguenti sorgenti di inquinamento atmosferico:

1. Biofiltro: composti tipici della fermentazione anaerobica della sostanza organica (NH<sub>3</sub>, H<sub>2</sub>S, sostanze odorigene);
2. Cogeneratore: prodotti della combustione del biogas (Polveri, HCl, COT, HF, NO<sub>x</sub>, CO).

I tempi delle lavorazioni e le quantità orarie di riferimento (materiale lavorato) previsti sono i seguenti:

| Sorgente     | Attività   | Durata attività | Quantità |
|--------------|--|-----------------|----------|
| Biofiltro    | Depurazione del flusso d'aria convogliato dal sistema di aspirazione del capannone di stoccaggio della FORSU | 24 h/g          | /        |
| Cogeneratore | Combustione del biogas e produzione di energia elettrica e termica utilizzate nellos tabilimento             | 24 h/g          | /        |

**Tab. 2** – Sorgenti significative di emissione individuate.

### 5.2 Definizione dei fattori di emissione

Al fine di poter effettuare una stima degli impatti prodotti dall'attività in esame è necessario, per ciascuna delle fasi, delle lavorazioni, delle tipologie di macchinario e delle rispettive modalità operative, poter disporre di specifici fattori di emissione. Tali dati possono, in alcuni casi, essere determinati da un'analisi bibliografica, in altri, dai database disponibili o dai risultati d'indagini specifiche effettuate in situazioni simili. Deve essere sottolineato che i fattori di emissione, qualora sufficientemente attendibili, sono utilizzati con lo scopo di caratterizzare le sorgenti stesse e determinarne, in prima approssimazione, le dimensioni degli ambiti d'impatto potenziale.

L'individuazione delle sorgenti e la determinazione dei fattori d'emissione ad esse legati, richiede un'analisi dettagliata del processo di lavorazione e dei mezzi utilizzati, secondo quanto descritto al

par. 5.1. Di seguito sono riportate le tipologie di sorgenti ritenute significative, per le quali è stato possibile effettuare delle ipotesi sulla definizione dei fattori di emissione specifici.

| Sorgente     | Descrizione emissione   | Tipo di sorgente     |
|--------------|---|----------------------|
| Biofiltro    | ▪ <u>Emissione convogliata</u> di NH <sub>3</sub> , H <sub>2</sub> S, Sostanze Odorigene provenienti dai primi processi di fermentazione anaerobica della FORSU all'interno del capannone di stoccaggio | <b>AREALE (E1)</b>   |
| Cogeneratore | ▪ <u>Emissione convogliata</u> dei fumi di combustione  | <b>PUNTUALE (E2)</b> |

**Tab. 3** – Definizione delle sorgenti.

### 5.2.1 Fattori di emissione per il “Biofiltro”

Al biofiltro viene convogliata l'aria di ricambio del capannone di stoccaggio della FORSU tramite idoneo sistema di aspirazione: la finalità del biofiltro è quella di abbattere i composti (NH<sub>3</sub>, H<sub>2</sub>S, Sostanze Odorigene) che si producono nelle prime fasi di decomposizione anaerobica del substrato organico. Dopo il passaggio sul biofiltro (E1) le esalazioni vengono espulse in atmosfera;

Gli “*Emission Rate*” in input al modello di calcolo sono stati calcolati a partire dai valori di flusso di massa degli inquinanti che si prevede di emettere dall'emissione E1, per il cui esercizio l'azienda ha inoltrato richiesta di rilascio di autorizzazione alle emissioni in atmosfera.

| Parametro          | Concentrazione (mg/Nm <sup>3</sup> )     | Flusso di massa (kg/h)     | Emission Rate (g/s*m <sup>2</sup> ) |
|--------------------|--|----------------------------|-------------------------------------|
| NH <sub>3</sub>    | 20,0                                     | 1,0                        | 8,38x10 <sup>-4</sup>               |
| H <sub>2</sub> S   | 4,5                                      | 0,2                        | 1,89 x10 <sup>-4</sup>              |
| Sostanze Odorigene | 220,0 (OU <sub>E</sub> Nm <sup>3</sup> ) | 3.055,6 OU <sub>E</sub> /s | 9,21                                |

**Tab. 4** – “*Emission Rate*” utilizzati nel modello di simulazione (Emissione E1).

### 5.2.2 Fattori di emissione per i “fumi di combustione del cogeneratore”

Anche per questa sorgente, gli “*Emission Rate*” sono stati definiti a partire dai valori di di flusso di massa degli inquinanti che si prevede di emettere dall'emissione E2, nel rispetto dei valori limite previsti dal D.M. 05/02/1998 – All. II – Suballegato I – Tipologia 2 – lett. a).

Per quanto riguarda la stima dell'emissione di NO<sub>2</sub> è stata considerata una quantità pari al 5% del totale degli NO<sub>x</sub>, come proposto dagli enti ed agenzie ambientali italiane (ARPA Veneto – Glossario dei rischi ambientali, ARPA Emilia Romagna – Rete di Monitoraggio della qualità dell'aria Report 2005).

| Parametro                        | Concentrazione (mg/Nm <sup>3</sup> ) | Flusso di massa (kg/h)                         | Emission Rate (g/s*m <sup>2</sup> )           |
|----------------------------------|--------------------------------------|--|---|
| Polveri                          | 8,0                                  | 1,04x10 <sup>-2</sup>                          | 2,88x10 <sup>-3</sup>                         |
| HCl                              | 10,0                                 | 1,29x10 <sup>-2</sup>                          | 3,59x10 <sup>-3</sup>                         |
| COT                              | 150,0                                | 1,94x10 <sup>-1</sup>                          | 5,39x10 <sup>-2</sup>                         |
| HF                               | 2,0                                  | 2,59x10 <sup>-3</sup>                          | 7,19x10 <sup>-4</sup>                         |
| NO <sub>x</sub> /NO <sub>2</sub> | 450,0 - 22,5                         | 5,82x10 <sup>-1</sup> - 2,91 x10 <sup>-2</sup> | 1,62x10 <sup>-1</sup> - 8,09x10 <sup>-3</sup> |
| CO                               | 500,0                                | 6,47x10 <sup>-1</sup>                          | 1,80x10 <sup>-1</sup>                         |

Tab. 5 – Emission Rate Cogeneratore.

### 5.3 Simulazione di ricaduta degli inquinanti

La previsione dell'impatto sulla qualità dell'aria dovuto all'attività in esame necessita, oltreché della caratterizzazione delle sorgenti, anche della definizione di scenari di medio e massimo impatto. Gli scenari considerati sono di seguito descritti.

Al fine di calcolare l'impatto dovuto alle sostanze rilasciate durante le fasi lavorative sono state rilevate le posizioni relative “sorgente - ricettore” sia in termini di distanza che di dislivello. In Fig. 3 sono indicate le sorgenti di emissione individuate presso lo stabilimento.

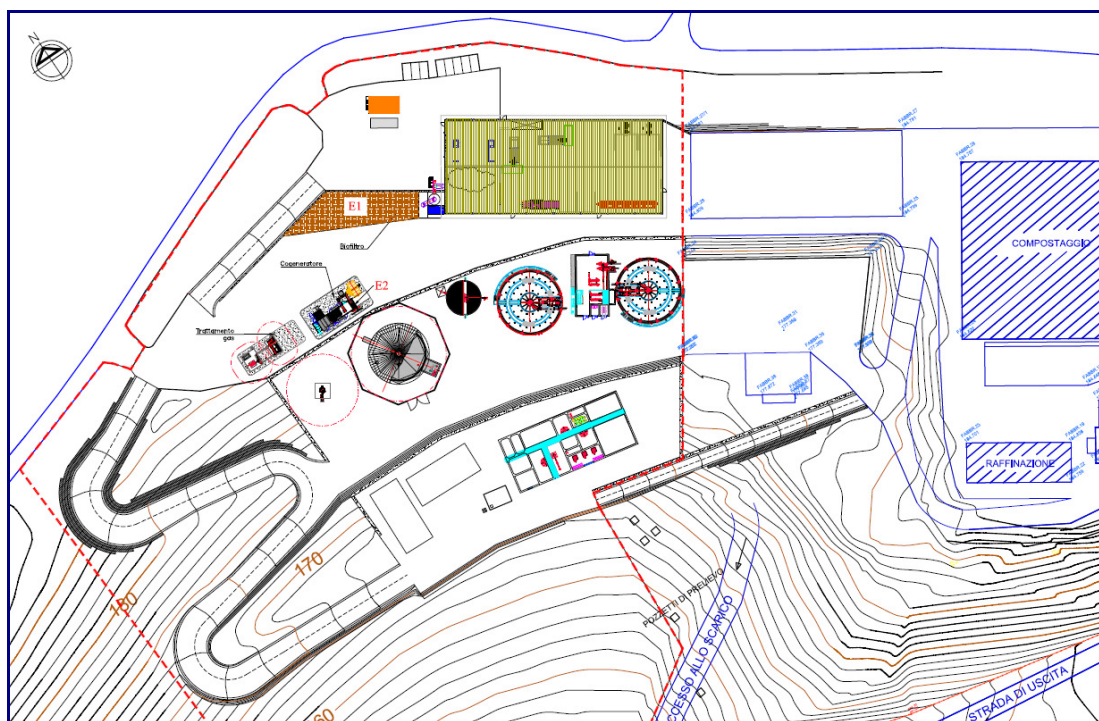

Fig. 3 – Localizzazione sorgenti.

Per valutare gli impatti delle singole sorgenti sono state rilevate le quote e le distanze dei ricettori sensibili dalle sorgenti. Le distanze e i dislivelli sorgente-ricettore sono riportati nella tabella che segue:

| Ricettore | Distanza da E1 | Distanza da E2 | Dislivello da E1 $\Delta$ (m) | Dislivello da E2 $\Delta$ (m) |
|-----------|----------------|----------------|-------------------------------|-------------------------------|
| RC1       | 140            | 145            | -10                           | -10                           |
| RC2       | 290            | 310            | +10                           | +10                           |

*Tab. 6 – Distanze e dislivelli sorgenti-ricettori.*

### 5.3.1 Impostazione del modello di simulazione

Per il calcolo delle ricadute degli inquinanti sono stati utilizzati i seguenti criteri:

- Per gli stessi inquinanti emessi da più fasi/attività identificabili con la medesima sorgente, l'Emission Rate in input al modello è costituito dalla somma dei singoli Emission Rate individuati per ciascun inquinante;
- Tutte le simulazioni sono state effettuate considerando il massimo livello di emissione oraria considerando le varie fasi di lavorazione continuative e contemporanee per tutto il tempo;
- Le concentrazioni di massima ricaduta al suolo sono state stimate nelle condizioni di dispersione più sfavorevoli per tutte le classi di stabilità atmosferica (classi di Pasquill) e alla luce della morfologia della zona;
- Il modello è stato impostato per il calcolo, lungo la direttrice scelta, del massimo inquinamento possibile per le diverse condizioni atmosferiche (es: calcolo della velocità del vento in grado di provocare la massima ricaduta al suolo) e tali risultanze sono state cautelativamente estese a tutte le direzioni;
- Le condizioni operative scelte in maniera peggiorativa rispetto alla realtà potranno verificarsi solamente per limitati periodi di tempo.

I dati di input al modello relativamente alle opzioni possibili sono stati i seguenti:

| Parametro                                 | u.m.               | E1                   | E2                   |
|---|--------------------|----------------------|----------------------|
|   |                    | Biofiltro            | Cogeneratore         |
| Source Type                               | /                  | Area                 | Point                |
| Dispersion Coefficient                    | /                  | Rural                | Rural                |
| Receptor Height Above Ground              | m                  | ± 10,0               | ± 10,0               |
| Emission Rate                             | g/s                | /                    | Vedi schede allegate |
|   | g/s*m <sup>2</sup> | Vedi schede allegate | /                    |
| Stack Height                              | m                  | /                    | 4,0                  |
| Stack Inside Diameter                     | m                  | /                    | 0,2                  |
| Stack Gas Exit Velocity                   | m/s                | /                    | 11,45                |
| Worst Case Meteorological Condition       | /                  | Yes                  | Yes                  |
| Conservative Brode 2 Mixing Height Option | /                  | Yes                  | Yes                  |

*Tab. 7 – Parametri di Input del modello.*

Per quanto concerne le parametrizzazioni impiegate per la simulazione, al fine di avere una valutazione nelle condizioni più sfavorevoli, i calcoli sono stati effettuati attivando le opzioni:

- “Worst Case Meteorological Condition”;
- “Conservative Brode 2 Mixing Height Option”.

La prima condizione fa sì che il modello di simulazione individui le condizioni di stabilità atmosferica e di velocità del vento in grado di provocare la massima concentrazione di ricaduta al suolo, per le diverse distanze, degli inquinanti emessi dalle sorgenti considerate.

Con la seconda, l'altezza dello strato di rimescolamento viene calcolata sui livelli minimi in relazione alla velocità del vento ed alla stabilità atmosferica considerate. L'impiego di tale opzione porta a stime conservative rispetto a modelli simili quali “ISCST US-EPA Model”.

L'opzione “RURAL” è stata scelta alla luce sia della natura del territorio sia perché la situazione che interessa prevalentemente monitorare è quella relativa all'area circostante lo stabilimento.

Nell'allegato A alla presente valutazione sono riportati i risultati di tutte le simulazioni di ricaduta degli inquinanti emessi per i diversi scenari ipotizzati. Le tabelle riportano, per ogni situazione simulata, i livelli di massima concentrazione di ricaduta al suolo attesi per le condizioni scelte alle diverse distanze dalle sorgenti, nonché le condizioni meteorologiche in cui le stesse si verificano.

### 5.3.2 Risultati della simulazione

Nei seguenti paragrafi si riportano i riepiloghi, a partire dalle schede di ricaduta elaborate per ciascun inquinante emesso dalle sorgenti per ciascuna classe di stabilità atmosferica, delle concentrazioni massime di ricaduta al suolo.

*Tab. 16 – Ricaduta CO.*

## 6 Confronto con i limiti di riferimento

La normativa di riferimento in tema di controllo della qualità dell'aria è costituita dal **D.Lgs. 155/2010** – “Attuazione della Direttiva 2008/50/CE relativa alla qualità dell'aria ambiente e per un'aria più pulita in Europa” che, all'art. 21 c. 1 lett. q, ha abrogato il D.M 60/2002 (Recepimento della Direttiva 1999/30/CE del Consiglio del 22 Aprile 1999 concernente i valori limite di qualità dell'aria ambiente per il Biossido di Zolfo, il Biossido di Azoto, gli Ossidi di Azoto, le particelle e il Piombo e della direttiva 2000/69/CE relativa ai valori limite di qualità dell'aria ambiente per il Benzene ed il Monossido di Carbonio) che stabiliva in precedenza i valori limite per la qualità dell'aria.

Il D.Lgs. 155/2010 stabilisce, all'allegato XI, i valori limite per NO<sub>2</sub>, CO, PM<sub>10</sub>, Pb e all'allegato XIII, i valori obiettivo per As, Cd e Ni nell'aria.

| Inquinante       | Valore limite | Valore obiettivo | u.m               | Periodo di mediazione |
|------------------|---------------|------------------|-------------------|-----------------------|
| PM <sub>10</sub> | 50            | /                | µg/m <sup>3</sup> | 24 h                  |
| CO               | 10            | /                | mg/m <sup>3</sup> | 8 h                   |
| NO <sub>2</sub>  | 200           | /                | µg/m <sup>3</sup> | 1 h                   |

**Tab. 17** – Valori limite e obiettivo per la qualità dell'aria.

In relazione alla ricaduta di HCl, HF, NH<sub>3</sub> e H<sub>2</sub>S non sono stati stabiliti limiti di concentrazione per la qualità dell'aria. Per l'impatto di tali inquinanti si è fatto riferimento ai livelli di tossicità TLV (*Threshold Limit Value*), nell'elaborazione TWA (*Time Weight Average* – media ponderata per un periodo di 8 ore) e in subordine nella forma STEL (*Short Term Exposure Limit* – valore massimo consentito per esposizioni <15'), stabiliti dall'allegato XXXVIII al D.Lgs. 81/08, laddove disponibili, altrimenti dalla ACGIH (*American Conference of Governmental Industrial Hygienists*).

| Inquinante       | TLV mg/m <sup>3</sup> | Elaborazione | Fonte                     |
|------------------|-----------------------|--------------|---------------------------|
| HCl              | 2,9                   | TLV – TWA    | D.Lgs. 81/08 All. XXXVIII |
| HF               | 1,5                   | TLV – TWA    | D.Lgs. 81/08 All. XXXVIII |
| NH <sub>3</sub>  | 14,0                  | TLV – TWA    | D.Lgs. 81/08 All. XXXVIII |
| H <sub>2</sub> S | 7,0                   | TLV – TWA    | D.Lgs. 81/08 All. XXXVIII |

**Tab. 18** – TLV di alcuni inquinanti.

In relazione alle Sostanze Odorigene si è fatto riferimento ai criteri di accettabilità proposti dalla Regione Lombardia nelle proprie linee guida che, per nuove attività o in caso di modifiche di impianti caratterizzate da emissioni di odori, prevedono che non debba essere superato il

seguente valore di concentrazione oraria di picco di odore al 98° percentile su base annuale:

- **4 OU<sub>E</sub>/m<sup>3</sup>** per aree agricole o industriali a 500 m. dal confine aziendale o al primo ricettore/potenziale ricettore.

Per quanto concerne gli scenari ipotizzati e descritti nei precedenti paragrafi è possibile prendere in considerazione, **come valori di assoluta cautela, i dati di concentrazione massima di ricaduta al suolo sul breve periodo** relativi alle simulazioni riportate nell'allegato A.

Dall'esame dei dati si evince che un'ampissima porzione del territorio interessato dall'attività della ASITE, che comprende tutti i recettori sensibili e la popolazione interessata, risulta essere esposta ad un incremento massimo potenziale del livello di inquinanti atmosferici molto modesto, con valori sempre al di sotto dei valori limite imposti.

Se si considera poi che:

- 1) I fattori di emissione si riferiscono a condizioni di funzionamento in contemporanea di tutti gli impianti ed alla massima potenzialità;
- 2) La ricaduta al suolo degli inquinanti è stata calcolata come valore massimo nell'ora;
- 3) Il fattore di emissione delle polveri è stato assunto come se l'intera frazione fosse costituita da PM<sub>10</sub>;
- 4) Nella simulazione è stata impostata una velocità del vento pari ad 1,0 m/sec (velocità raccomandata dall'US-EPA come quella per la quale si verificano le peggiori condizioni di ricaduta al suolo degli inquinanti) sicuramente penalizzante ai fini del presente studio;

è possibile affermare che **lo scenario di ricaduta degli inquinanti presso i ricettori sensibili considerati sarà sicuramente migliore rispetto a quello valutato in via previsionale.**

## 7 Conclusioni

Per avere un quadro più generale e realistico della situazione, è necessario considerare quanto segue:

- **I valori di concentrazione massimi possibili di inquinanti, attesi alla quota dei recettori più esposti e più prossimi**, si verificano, come valutato dal modello, in condizioni prevalenti di **neutralità atmosferica**, corrispondente alla classe di stabilità atmosferica di Pasquill D. Tali condizioni sono possibili nelle ore notturne, o diurne con scarsa radiazione solare, sostenuta velocità del vento (>5 m/s) con associati fenomeni di “*Wind Shear*” e cielo coperto da densa coltre nuvolosa, una combinazione di eventi atmosferici che non è certamente la più frequente dal punto di vista statistico. Nella maggioranza dei casi, pertanto, vi sarà nell’area una **condizione meteorologica diversa da quella di massima ricaduta**;
- Le **ipotesi di calcolo partono da dati di massima emissione possibile** nelle condizioni “*Worst Case Meteorological Condition*”;
- Nelle equazioni del modello si assume che **gli inquinanti non subiscano trasformazioni chimiche e non avvengono processi di rimozione durante la dispersione in atmosfera**;
- La distribuzione spaziale delle ricadute, **calcolate puntualmente e nel loro valore massimo possibile**, nella realtà interesserà vari settori di area con una variabilità sia nell’arco della giornata (variabilità dei regimi anemometrici causata dall’orografia dell’area), sia nelle diverse stagioni dell’anno (variabilità dell’intensità della radiazione solare incidente) che garantirà una dispersione su più settori degli inquinanti e livelli puntuali di concentrazione, sia su base giornaliera che oraria, sensibilmente più bassi. Inoltre **tali incrementi potranno**, in relazione alle diverse condizioni meteorologiche, **verificarsi con bassa frequenza ed interessare porzioni di territorio limitate**: in sostanza la ricaduta non interesserà sempre tutti i recettori ma solo quelli esposti riducendo ulteriormente il tempo di esposizione dei singoli recettori all’impatto dell’impianto;

Pertanto, tenendo conto delle valutazioni e delle considerazioni fatte, si ritiene sia possibile concludere che, **nelle condizioni operative previste, anche ipotizzando che l’attività si svolga sempre al massimo della potenzialità possibile:**

1. **gli incrementi massimi di concentrazione di  $\text{NH}_3$**  nell’aria dovuti all’attività in esame, riferiti alla media oraria per singolo settore di territorio, sono stimati **non superiori a 0,2  $\text{mg}/\text{m}^3$**  per il ricettore RC1 e **0,3  $\text{mg}/\text{m}^3$**  per il ricettore RC2, pari a **1,5% e 2,1% rispettivamente** del TLV-TWA stabilito dall’Al. XXXVIII al D.Lgs. 81/2008;

2. **gli incrementi massimi di concentrazione di H<sub>2</sub>S** nell'aria dovuti all'attività in esame, referiti alla media oraria per singolo settore di territorio, sono stimati **non superiori a 0,07 mg/m<sup>3</sup>** pari a **1,0%** del TLV-TWA stabilito dall'All. XXXVIII al D.Lgs. 81/2008;
3. **i massimi livelli di odore nell'aria** dovuti all'attività in esame, referiti alla media oraria per singolo settore di territorio, sono stimati **non superiori a 4 OU<sub>E</sub>/m<sup>3</sup>**, quale valore di accettabilità stabilito dalle linee guida della Regione Lombardia;
4. **gli incrementi massimi di concentrazione di PM<sub>10</sub>** nell'aria dovuti all'attività in esame, referiti alla media oraria per singolo settore di territorio, sono stimati **non superiori a 2,8 µg/m<sup>3</sup>** per il ricettore RC1 e **1,0 µg/m<sup>3</sup>** per il ricettore RC2 **corrispondenti al 5,6% e 2,0% rispettivamente del valore limite giornaliero** fissato dal D.Lgs. 155/2010;
5. **gli incrementi massimi di concentrazione di HCl** nell'aria dovuti all'attività in esame, referiti alla media oraria per singolo settore di territorio, sono stimati **non superiori a 3,5 µg/m<sup>3</sup>** per il ricettore RC1 e **1,3 µg/m<sup>3</sup>** per il ricettore RC2, pari a **0,04% e 0,01% rispettivamente** del TLV-TWA stabilito dall'All. XXXVIII al D.Lgs. 81/2008;
6. **gli incrementi massimi di concentrazione di composti organici (espressi come COT)** nell'aria dovuti all'attività in esame, referiti alla media oraria per singolo settore di territorio, sono stimati **non superiori a 0,052 mg/m<sup>3</sup>** per il ricettore RC1 e **0,020 mg/m<sup>3</sup>** per il ricettore RC2;
7. **gli incrementi massimi di concentrazione di HF** nell'aria dovuti all'attività in esame, referiti alla media oraria per singolo settore di territorio, sono stimati **non superiori 0,7 µg/m<sup>3</sup>** per il ricettore RC1 e **0,2 µg/m<sup>3</sup>** per il ricettore RC2, pari a **0,04% e 0,01% rispettivamente** del TLV-TWA stabilito dall'All. XXXVIII al D.Lgs. 81/2008;
8. **gli incrementi massimi di concentrazione di NO<sub>2</sub>** nell'aria dovuti all'attività in esame, referiti alla media oraria per singolo settore di territorio, sono stimati **non superiori 7,9 µg/m<sup>3</sup>** per il ricettore RC1 e **3,0 µg/m<sup>3</sup>** per il ricettore RC2 **corrispondenti a 3,9% e 1,5% rispettivamente del valore limite orario** fissato dalla vigente normativa;
9. **gli incrementi massimi di concentrazione di CO** nell'aria dovuti all'attività in esame, referiti alla media oraria per singolo settore di territorio, sono stimati **non superiori a 0,17 mg/m<sup>3</sup>** per il ricettore RC1 e **0,067 mg/m<sup>3</sup>** per il ricettore RC2 **corrispondenti a 1,7% e 0,7% rispettivamente del valore limite sulle 8 h** fissato dalla vigente normativa;

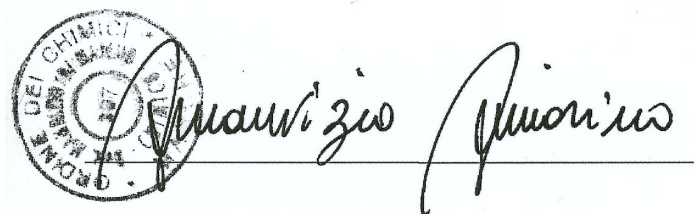

Alla luce di tutto quanto sopra esposto è pertanto possibile ritenere che **le concentrazioni di ricaduta degli inquinanti atmosferici** emessi dall'attività oggetto del presente studio, considerate anche le modalità ed i tempi di lavorazione previsti e la limitatezza spaziale del territorio interessato dal fenomeno, **sono da ritenersi tali da non modificare significativamente lo stato della qualità dell'aria della zona e garantire il mantenimento del rispetto dei valori limite** imposti dal D.Lgs. 155/2010.

## 8 Allegati – Schede di ricaduta degli inquinanti

Si allegano alla presente valutazione n° 54 schede di simulazione di massima ricaduta degli inquinanti.

Macerata, lì 27/03/2014
